**OVERVIEW**

**Overview**

## OVERVIEW

This report contains population projections for Tennessee cities and counties in five-year intervals from 2010 to 2030. The purpose of the projections is to aid in local planning efforts, such as those outlined in Public Chapter 1101 (PC1101).

The Center for Business and Economic Research (CBER) previously released population projections for cities, counties and unincorporated areas in 1998 and 2003. Both the 2003 and 2009 projections use the *cohort component* method to determine future population trends. This approach models the components of population change, including births, deaths, and migration, and results in population counts by sex and 5-year age group. Because of space limitations, only population totals for the state, county or place are included in this report. Further details on this model may be found in the Technical Appendix.

Like the previous study, this study uses county-level population projections to control both the state and city-level population counts. In other words, first county population projections are created. The county results are summed together to create the state population projections. In both studies, the city-level projections were weighted so that they were equal to the county totals.

There are some notable differences between the current approach and previous efforts. In the 2003 study, city-level Census data for 2000, 2001 and 2002, were used to assign a share of the county estimates to each city. The current approach uses the cohort component method on the city-level data rather than disaggregating these estimates from county totals. The population projections are generated in four steps. First, a range of fertility and mortality rates are used to predict the number of births and deaths in each county between 2000 and 2004. The fertility/mortality rate that is selected is the one that results in the smallest difference between predicted births/deaths and actual births/deaths over the 2000 to 2004 time period. Second, county-level projections are created using the cohort component method. Third, we apply the cohort component method to the place population as reported in the 2000 Census. Finally, the city-level projections are re-weighted so they are consistent with the county-level population projections.

Population projections rely on using fertility, mortality and migration rates from the past that will likely persist in the future. Unlike fertility and mortality rates, which exhibit largely consistent trends, migration patterns are extremely difficult to predict. While migration is always volatile, the recent changes that both the national and state economy have experienced will no doubt impact migration patterns in the near-term, and perhaps in the long-term as well. In many counties, the fertility rate is not high enough to sustain population growth in the absence of migration, making the number of new migrants especially important in determining future changes in the community. The population projections presented in this report rely on the migration patterns in Tennessee from 1990 to 2005. The more future migration, fertility or mortality diverges from the recent past, the less accurate population projections will be.

Because future migration is so difficult to determine over the long term, migration rates in this study are dampened from 2015 onwards. The Census uses the same process when creating their long-term population projections. The purpose is to lessen the effects of particularly high and low migration rates, both of which are unlikely to persist over a long time period. One of the consequences of reducing migration rates can be population decreases after a period of population growth. Decreasing migration rates are not the sole cause of population decline. In many counties, fertility rates have declined, and deaths exceed or will exceed births. Both changes in migration and changes in a county's age structure – which impacts the number of women of child-bearing age – can impact whether there is population growth or decline.

## OVERVIEW

The projections included in this report rely exclusively on population measures – an initial population from the 2000 Census, and historic fertility, mortality and migration rates. Because of this, important factors such as space constraints for new housing, zoning rules, water availability, and road capacity in no way limit population numbers. Just as these factors do not limit growth, neither do they generate growth. The population projections will be most in error in those counties and cities where new industries or housing developments alter the prevailing migration rates of the last 15 years.

In addition to providing projections at the level of cities, CBER also explored creating population projections for individual PC1101 regions, such as municipalities, urban growth boundaries, planned growth areas and rural areas. There were two major obstacles that precluded the creation of population projections in this format. First, there is no straightforward way to ensure that the original PC1101 maps, which were submitted to the Local Government Planning Advisory Committee as paper maps, are drawn so that the Census population captured by the municipalities, urban growth boundaries, planned growth areas and rural areas are the way map-makers intended. Second, it was impossible to make certain that the paper PC1101 maps have been faithfully translated into digital maps. There are good reasons to believe that one or both of these assumptions will not hold true for every county or PC1101 area. More importantly, it is impossible to systematically evaluate areas where these assumptions hold true, and areas where they do not. For this reason, only population projections by municipalities are being released.

**APPENDIX**

**Technical Appendix**

## APPENDIX

### *Cohort Component Method*

The approach used to generate the population projections in this report is the cohort component method. Implementing this method depends on two kinds of data: an accurate count of the number of people at the beginning of a projection period, and a way to reliably predict the components of population change - births, deaths and migration. The application of the model proceeds in two conceptual steps. First, we construct the *cohort* - a group of individuals who were born within the same 5-year period, disaggregated by sex and place of residence. Next, we apply age-specific birth, death and migration rates to each cohort, which results in the total population 5 years in the future.

The initial cohorts are constructed using data from the 2000 Census – the last year in which there was a complete enumeration of the population by age, sex and place of residence. Determining which data to use for constructing the fertility, mortality and migration rates is less straight-forward. The approach for fertility and mortality was to select rates that best predict the number of births and deaths, by county, from 2000 to 2004. Migration rates also apply to the county-level. A more detailed explanation of the methods employed to select county-appropriate rates is described below.

There is no single agency that collects and releases this information at the same geographic scale (counties and places) or time scale (some rates are before the year 2000 and some after) as the Census data. Like the nation as a whole, Tennessee's fertility rates have recently reached their highest levels in over a decade. In mortality the state contradicts national trends - while many states have experienced decreases in mortality rates in recent years, Tennessee has not. Whether the high fertility and mortality rates over the last few years will continue is unknown; anticipating the timing and magnitude of these changes requires additional modeling that is outside the scope of this report. As described in the section below, some efforts have been made to account for county-level differences in fertility and mortality - these rates are time-invariant, but they do reflect some of the differences in fertility and mortality in the state of Tennessee.

### *From County to Place to Growth Boundaries*

Creating sub-county population projections is difficult due to a lack of data, small population counts, and yearly fluctuations in births, deaths and migrants. The Census publishes population estimates for cities and towns (Census places) annually. However, the more time that has passed since the last decennial Census, the more error in these estimates as illustrated by examining the place estimates the year of a Census versus the actual place-based Census counts.

The sub-county population projections occurred in two steps. First we created county-level population projections by 5-year age group and sex in 5-year intervals from 2000 to 2030. We weighted the 2005 population projections to be equal to the 2005 county-level estimates reported by the Census Bureau. Next, we generated place-based population projections, in the same sex and age groups as the county-level projections, using the 2000 Census place data as the baseline. We weighted these estimates so that the place-based projections were equal to the county-based projections for every age and sex combination. For example, the total count of 10-14 year old boys for all places in a county in 2015 will be equal to the county total of 10-14 year old boys in 2015.

### *Baseline Population*

Census Bureau data for 2000 was used to construct the baseline population, including the population count by age, sex and county. When used to predict future population, these counts needed to be modified to reflect special populations, i.e. those residing in group quarters such as prisons, nursing

## APPENDIX

homes and military bases, and those enrolled in colleges. Special consideration is necessary for these populations because they experience life events differently than the non-group quarter population. For example, consider counties with a large college student population. Without changing the base population to reflect that most college students move to school, graduate or drop out, then move away, a “bulge” of 15-24 year olds stays in the county, leading to a higher number of births than expected and, in 5 years’ time, a higher number of 20-29 year olds than expected. To account for these changes, the special populations are subtracted from the baseline population, fertility, mortality and migration rates are applied, and the special population totals are then added back in to obtain each county’s (or place’s) total population.

The total number of individuals residing in group quarters is available by age (under 18, 18-64 and 65 plus), sex and county. To be used in the cohort component model, the group quarters data need to be allocated across 5-year age groups. The assumptions made in distributing the group quarters data into the appropriate age categories are described below.

### College population

In those counties where the undergraduate population represented 5 percent or more of the local population, special Census tabulations were used for establishing a count of college students. In these counties, 25 percent of the undergraduate population was assigned to the 15-19 age group, and 75 percent was assigned to the 20-24 age group.

### Group Quarters population

The under-18 group quarters population was equally distributed across the 10-14 and 15-19 age groups. In the 18-64 group quarters population, most individuals lived in college dormitories, correctional facilities or military bases. Those listed as living in college dormitories were already accounted for in the undergraduate student population. The non-college dormitory population, which includes those in prison and those living on military bases, was distributed across age groups according to a 2008 Census of the prison population by the Tennessee Department of Corrections for prisons<sup>1</sup>, and according to a Census of military personnel for those residing on military bases<sup>2</sup>. The over-65 group quarters population was largely comprised of those living in nursing homes. This population was distributed to age groups according to a nursing home statistics reported by the National Center for Health Statistics<sup>3</sup>.

When the cohort component model is implemented, the college/group quarters population totals estimated here are subtracted from the base population. Next, the fertility, mortality and migration rates are applied to the amended population totals. This results in the initial population projection. Finally, the college/group quarters population is added back to the initial population projections in order to obtain the final total population.

<sup>1</sup> The prison population was distributed across age groups according to the report “FY08 Statistical Abstract” prepared by the Tennessee Department of Corrections. Available online: <http://www.state.tn.us/correction/pdf/2008%20Statabs.pdf>

<sup>2</sup> The population on military bases was distributed by age group according to Appendix B “Active Component Enlisted Accessions, Enlisted Force, Officer Accessions, and Officer Corps Tables,” included in the report “Population Representation in the Military Services, 2006.” Available online: [http://www.defenselink.mil/prhome/PopRep\\_FY06/download.html](http://www.defenselink.mil/prhome/PopRep_FY06/download.html)

<sup>3</sup> The nursing home population was distributed to age groups according to Table 104 in the report “Health, United States, 2007,” published by the United States Department of Health and Human Services. Available online: <http://www.cdc.gov/nchs/data/hus/07.pdf#104>

## APPENDIX

### *Mortality*

When predicting the number of deaths that will occur over a 5-year time period, the cohort component method uses survival rates derived from life tables rather than age-specific mortality rates. Constructing life tables is more labor-intensive than simply using mortality rates, and these data are not released at the sub-state level for Tennessee. Three life table survival rates were considered when modeling mortality; state-level data for Tennessee from 1989-1991 (this is the last year in which the United States' National Center for Health Statistics released state-level life tables), national-level data for the United States for 1999-2001 created by the National Center for Health Statistics, and state-level data released by the Tennessee Department Health for 1995. For purposes of creating projections, state-level survival rates calculated by the state and the federal government were considered. The survival rate that best predicted the number of county-level deaths from 2000 to 2004 was selected.

### *Migration*

Measuring past and future migration flows to Tennessee are complicated by their high variability. Two sets of net migration rates were consulted for constructing migration: Census-constructed net migration rates from 1990 and 2000 by age, sex, and county, and CBER-calculated net migration rates between 2000 and 2005 by age, sex and county. The CBER-calculated rates were derived by applying birth and fertility rates to the 2000 Census population to generate the 2005 population. The difference between the 2005 Census county population estimates and the modeled 2005 population was assumed to be net migration. The 1990-2000 Census migration rates were combined with the 2000 to 2005 CBER net migration rates to establish an average 5-year net migration rate. To reflect current economic conditions, to be consistent with the Census' long-term estimate of migration, and to dampen the effects of the particularly high migration from 1990 to 2000, the net migration rate decreases over time.

### *Fertility*

The Tennessee Department of Health reports county-level fertility rates annually. Due to the yearly variability in fertility rates, selecting which rates to use is difficult. A list of possible fertility rates was available from the Tennessee Department of Vital Statistics that included both state- and county-level fertility rates. Three-year state-level averages included the years 1991-1993, 1994-1996, 1997-1999, 2000-2002, and 2003-2005, while county-level rates for 1990-1994, 1995-1999, and 2000-2004 were considered.

The average rate that best predicted the number of county-level births from 2000 to 2004 was selected for projecting total births in all subsequent projection periods.

**APPENDIX**

**Total Projections for Municipalities**
